Objective:

Create a simple Angular application that fetches data from the Pokémon API and displays information about Pokémon.

Requirements:

Pokémon List Page:

Display a list of Pokémon fetched from the API.
Each Pokémon item should display its name and sprite (image).

Pokémon Details Page:

When a Pokémon item is clicked, navigate to a details page displaying more information about that Pokémon.
Display the Pokémon's name, sprite, types, abilities, and any other relevant information you find interesting.
Include a back button to return to the Pokémon list page.

Search Feature:

Implement a search feature allowing users to search for Pokémon by name.
The search should dynamically filter the Pokémon list as the user types.

Styling:

Apply basic styling to make the application visually appealing.
Ensure the application is responsive and looks good on different screen sizes.

Error Handling:

Handle errors gracefully, displaying a meaningful message to the user if something goes wrong while fetching data from the API.

Testing:

Write unit tests for critical components to ensure their functionality.

Guidelines:

Use Angular framework for building the application.
You can use any additional libraries or tools you find necessary.
Focus on writing clean, modular, and maintainable code.
Pay attention to user experience and interface design.
Host your project on GitHub and provide clear instructions on how to run it locally.

Evaluation Criteria:

Code Quality: Is your code clean, well-structured, and maintainable?
User Experience: Is the application easy to use and visually appealing?
Error Handling: Did you handle errors effectively?
